Psoriasis is a chronic disease affecting the skin and joints. It can have a significant impact on the physical, emotional, and psychosocial wellbeing of the patients.

**OBJECTIVE**

To determine the epidemiology and clinical characteristics in adult patients (aged >18 years) with psoriasis in Malaysia.

**METHOD**

Data was obtained from the Malaysian Psoriasis Registry between July 2007 and Dec 2016.

**RESULTS**

A total of 15,794 adult patients were notified to the registry between July 2007 and December 2016. 56.6% of the patients were male and 50.5% of the patients were Malay. Mean age of the patients was 36.1 ± 17.1 years. 23.2% of patients had positive family history of psoriasis. Plaque psoriasis was the commonest type of psoriasis (85.1%), followed by guttate psoriasis (2.9%) and erythrodermic psoriasis (1.7%) (Figure 1). Psoriatic arthropathy was reported in 13.7% of patients (Figure 2). 57.1% patients had nail involvement (Figure 3). Most of the patients (93.3%) were on topical treatment (Figure 4). Only 2.8% of patients received phototherapy and NB-UVB was the commonest used (87.5%) (Figure 5). Systemic therapy was given in 18.4% of patients and the commonest systemic agent used was methotrexate (74.0%) (Figure 6). The mean DLQI score was 8.5 ± 6.6 (Figure 7).

**CONCLUSION**

Data from the Malaysian Psoriasis Registry reported a slight male preponderance among adult patients with psoriasis in Malaysia. Plaque psoriasis contributes to 85.1% of adult patients with psoriasis, and 13.7% of patients had psoriatic arthritis. Majority of the patients were on topical treatment (93.3%), followed by systemic agents (18.4%) and phototherapy (2.8%). It is important to note the moderate impairment in the quality of life in adult patients with psoriasis.

**ACKNOWLEDGEMENT**

We would like to thank all doctors and allied health personnel from the participating centres. We also acknowledge the support of Clinical Research Centre, Ministry of Health Malaysia and Dermatological Society of Malaysia.
